Jira backlog with Epics and User Stories:

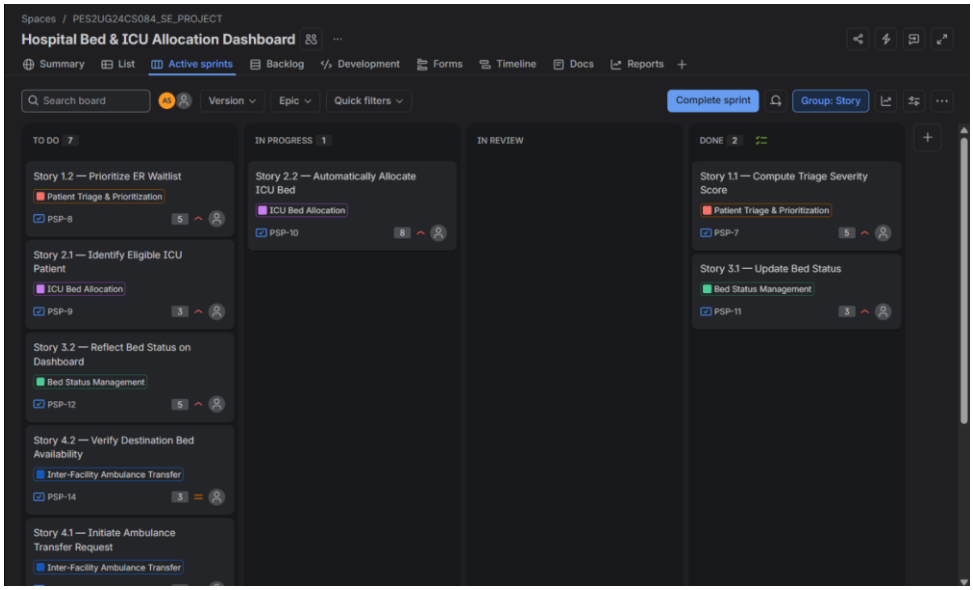

Story point assignments.

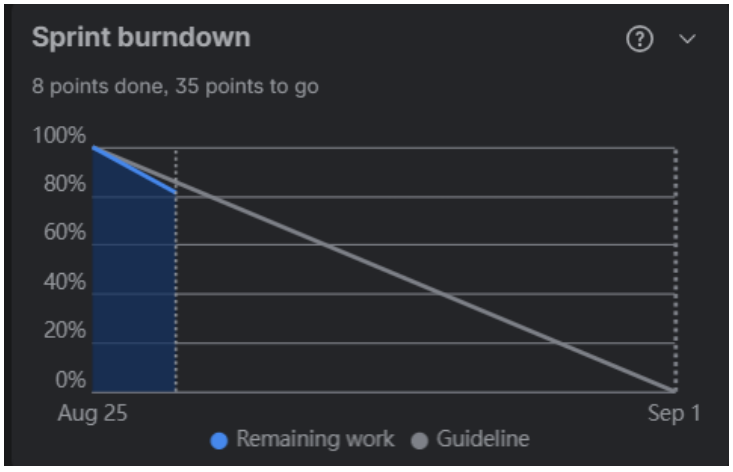

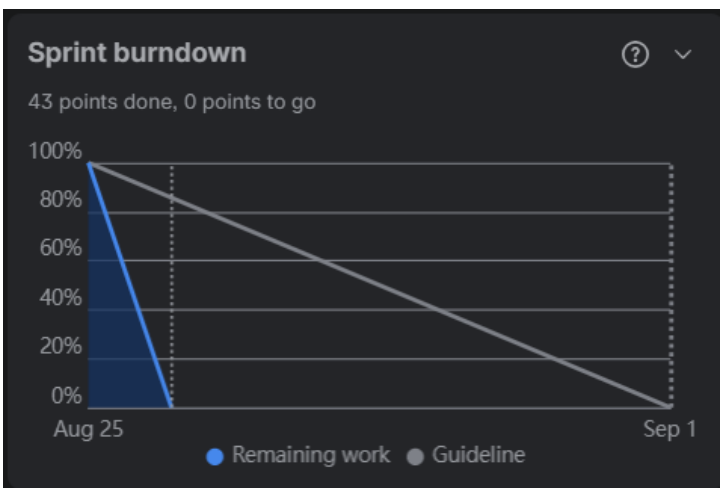

Sprint board (Active Sprint view).

Burndown Chart

Reflection Questions:

Q) Did your estimations reflect the actual effort?

Yes, to a reasonable extent**.** The story points provided a useful relative estimate of the effort required for each task/ user story. More complex functionality, such as automatic allocation of an ICU bed, was assigned 8 points, while simpler tasks such as updating bed status or viewing occupancy were assigned 3 points. Since the sprint was simulated rather than a real development sprint, the story points could not be compared against actual implementation hours. However, the estimates were useful for distinguishing between high-complexity and low-complexity tasks and for planning the sprint workload.

Q) Was your backlog well-prioritized?

Yes; the backlog was prioritized according to the importance and user impact of each functionality. Critical patient-care functionality, such as computing triage severity, prioritizing the ER waitlist, identifying eligible ICU patients, and automatically allocating ICU beds, was placed toward the top of the backlog. Supporting functionality, such as occupancy viewing and filtering, was placed lower. This ensured that the most important hospital operations would be addressed before secondary monitoring and reporting features.

Q) How did your simulated sprint align with your plan?

The simulated sprint largely aligned with the planned backlog. The 10 User Stories were selected for Sprint 1 and assigned a total of 43 story points. During the sprint simulation, the stories were moved through the workflow from To Do to In Progress and then to Done. The sprint initially showed 8 points completed and 35 points remaining on the burndown chart, and the remaining stories were subsequently completed. This demonstrated that the planned backlog could be progressed through the Scrum workflow as expected. However, because the sprint was simulated, the results represent a demonstration of the Agile process rather than actual development performance.

Q) What insights did the burndown chart give about your team's capacity?

The burndown chart showed how the team's remaining workload changed as User Stories were completed. At the point when the chart was captured, 8 story points had been completed and 35 points remained out of the original 43 points. The chart provided a comparison between actual remaining work and the ideal guideline, making it easier to determine whether the sprint was progressing at the expected rate. It also demonstrated that completing work progressively reduces the remaining workload and helps assess whether the planned sprint capacity is realistic. Since this was a simulated sprint completed in a compressed period, the chart should be interpreted as a demonstration of sprint tracking rather than a reliable measure of real team capacity.
